### Activity Assign Python variables

October 27, 2025

### 1 Activity: Assign Python variables

#### 1.1 Introduction

Variables help security analysts to keep track of a variety of security-related information. For example, analysts may need to create Python variables for the users who are allowed to log in, the number of login attempts that they're permitted, and the current number of attempts that a user has made.

In this lab, you'll practice assigning values to variables and determining their data types.

Tips for completing this lab

As you navigate this lab, keep the following tips in mind:

- ### YOUR CODE HERE ### indicates where you should write code. Be sure to replace this with your own code before running the code cell.
- Feel free to open the hints for additional guidance as you work on each task.
- To enter your answer to a question, double-click the markdown cell to edit. Be sure to replace the "[Double-click to enter your responses here.]" with your own answer.
- You can save your work manually by clicking File and then Save in the menu bar at the top of the notebook.
- You can download your work locally by clicking File and then Download and then specifying your preferred file format in the menu bar at the top of the notebook.

### 1.2 Scenario

You are a security analyst who is responsible for writing code that will automate analysis of login attempts made to a specific device. As the first step, you'll need to create variables to keep track of information relevant to the login process. This information includes the device ID, list of approved usernames, maximum login attempts allowed per user, current login attempts made by a user, and login status.

Throughout this lab, you'll assign these variables and check the data types of the variables.

#### 1.3 Task 1

In your work as an analyst, imagine there is a device only users specified on an allow list can access, and its device ID is "72e08x0".

In the following code cell, assign this value to a variable named device\_id. Then, display the contents of the variable and observe the output.

Be sure to replace each ### YOUR CODE HERE ### with your own code before you run the following cell.

#### 72e08x0

Hint 1

Use quotation marks around the value that you assign to the device\_id variable.

Hint 2

Assign the value "72e08x0" to the variable device\_id. To do this, place the value to right of the = operator.

Hint 3

To display the contents of device\_id, place the name of this variable inside the print() function.

#### 1.4 Task 2

Now that the variable device\_id is defined, you can return its data type.

In this task, use a Python function to find the data type of the variable device\_id. Store the data type in another variable called device\_id\_type. Then, display device\_id\_type to examine the output.

Be sure to replace each ### YOUR CODE HERE ### with your own code before you run the following cell.

```
[20]: # Assign the `device_id` variable to the device ID that only specified users

device_id = "72e08x0"

# Assign `device_id_type` to the data type of `device_id`

device_id_type = type(device_id)

# Display `device_id_type`
```

```
print(device_id_type)
```

<class 'str'>

Hint 1

The type() function allows you to get the data type of a given value.

Hint 2

Use type(device\_id) to get the data type of the device\_id variable.

Hint 3

To display device\_id\_type, place the name of this variable inside the print() function.

# Question 1 Based on the output above, what do you observe about the data type of device\_id?

After puting type to device\_id\_type and then inserting the device\_id to it, it outputs <class 'str'> when device\_id\_type is called. This means it is a string type.

#### 1.5 Task 3

As you continue your work, you're provided a list of usernames of users who are allowed to access the device. The usernames with this access are "madebowa", "jnguyen", "tbecker", "nhersh", and "redwards".

In this task, create a variable called username\_list. Assign a list with the approved usernames to this variable. Then, display the value of the username\_list variable.

Be sure to replace each ### YOUR CODE HERE ### with your own code before you run the following cell.

```
[21]: # Assign `username_list` to the list of usernames who are allowed to access the username_list = ["madebowa", "jnguyen", "tbecker", "nhersh", "redwards"]

# Display `username_list`
print(username_list)
```

['madebowa', 'jnguyen', 'tbecker', 'nhersh', 'redwards']

Hint 1

To create a list in Python, use square brackets. Inside the square brackets, write the elements of the list, with a comma between elements.

To assign a value to a variable in Python, place the name of the variable to the left of the = operator, and place the value to the right of the = operator.

In this task, make sure to place ["madebowa", "jnguyen", "tbecker", "nhersh", "redwards"] to the right of the = operator.

Hint 3

To display username\_list, place the name of this variable inside the print() function.

#### 1.6 Task 4

In this task, find the data type of the username\_list. Store the type in a variable called username\_list\_type. Then, display username\_list\_type to examine the output.

Be sure to replace each ### YOUR CODE HERE ### with your own code before you run the following cell.

```
Answer:
```

<class 'list'>
Now for Alt (Specific) is below:
<class 'str'>

Hint 1

The type() function allows you to get the data type of a given value.

Hint 2

To get the data type of username\_list, call the type() function and pass in username\_list.

In Python, you can use the print() function to display the value of a variable. To display username\_list\_type, call the print() function and pass in username\_list\_type.

# Question 2 Based on the output above, what do you observe about the data type of username\_list?

After puting type to username\_list\_type and then inserting the username\_list to it, it outputs <class 'list'> when username\_list\_type is called. This means it is a list type. However, if you change the code as below the print to alternative method and be very specific of what is username\_list like username\_list[0], you will get the type of the first element in the list which is a string type.

#### 1.7 Task 5

Now, imagine that you've been informed that the previous list is not up-to-date and that there is another employee that now has access to the device. You're given the updated list of usernames with access, including the new employee, as follows: "madebowa", "jnguyen", "tbecker", "nhersh", "redwards", and "lpope".

In this task, reassign the variable username\_list to the new list. Run the code to display the list before and after it's been updated to observe the difference.

Be sure to replace each ### YOUR CODE HERE ### with your own code before you run the following cell.

```
['madebowa', 'jnguyen', 'tbecker', 'nhersh', 'redwards']
['madebowa', 'jnguyen', 'tbecker', 'nhersh', 'redwards', 'lpope']
```

When reassigning a variable to a new value in Python, place the name of the variable to the left of the = operator, just as you would when assigning the variable for the first time.

#### Hint 2

To reassign username\_list to the updated list, place username\_list to the left of the = operator.

## Question 3 Based on the output above, what do you observe about the contents of username\_list?

After putting type to username\_list and then printing out username\_list to it, it outputs ['madebowa', 'jnguyen', 'tbecker', 'nhersh', 'redwards'] when username\_list is called. The second one, I noticed just change the list but when called it has a differnt output. After puting type to username\_list and then printing out username\_list to it, it outputs ['madebowa', 'jnguyen', 'tbecker', 'nhersh', 'redwards', 'lpope'] when username\_list is called.

### 1.8 Task 6

In this task, define a variable called max\_logins that represents the maximum number of login attempts allowed per user. Store the value 3 in this variable. Then, store its data type in another variable called max\_logins\_type. Display max\_logins\_type to examine the output.

Be sure to replace each ### YOUR CODE HERE ### with your own code before you run the following cell.

```
[24]: # Assign `max_logins` to the value 3

max_logins = 3

# Assign `max_logins_type` to the data type of `max_logins`

max_logins_type = type(max_logins)

# Display `max_logins_type`

print(max_logins_type)
```

<class 'int'>

### Hint 1

When assigning a value to a variable in Python, use the = operator. Place the name of the variable to the left of the = operator, and place the value to the right of the = operator.

#### Hint 2

To assign 3 to max\_logins, place max\_logins to the left of the = operator, and place 3 to the right of the = operator.

To assign max\_logins\_type, place max\_logins\_type to the left of the = operator before the type() function call.

Hint 3

In Python, you can use the print() function to display the value of a variable. To display max\_logins\_type, call print() and pass in max\_logins\_type.

# Question 4 Based on the output above, what do you observe about the data type of max\_logins?

After puting type to max\_logins\_type and then inserting the max\_logins to it, it outputs <class 'int'> when max\_logins\_type is called. This means it is an integer type.

#### 1.9 Task 7

In this task, define a variable called login\_attempts that represents the current number of login attempts made by a user. Store the value 2 in this variable. Then, store its data type in a variable called login\_attempts\_type. Display login\_attempts\_type to observe the output.

Be sure to replace each ### YOUR CODE HERE ### with your own code before you run the following cell.

```
[25]: # Assign `login_attempts` to the value 2

login_attempts = 2

# Assign `login_attempts_type` to the data type of `login_attempts`

login_attempts_type = type(login_attempts)

# Display `login_attempts_type`

print(login_attempts_type)
```

<class 'int'>

Hint 1

When assigning a value to a variable in Python, use the = operator. Place the name of the variable to the left of the = operator, and place the value to the right of the = operator.

Hint 2

To assign 2 to login\_attempts, place login\_attempts to the left of the = operator, and place 2 to the right of the = operator.

To assign login\_attempts\_type, place login\_attempts\_type to the left of the = operator, and place a call to the type() function to the right of the = operator.

When calling type(), make sure to pass in login\_attempts.

In Python, you can use the print() function to display the value of a variable. To display login\_attempts\_type, call print() and pass in login\_attempts\_type.

# Question 5 Based on the output above, what do you observe about the data type of login\_attempts?

After puting type to login\_attempts\_type and then inserting the login\_attempts to it, it outputs <class 'int'> when login\_attempts\_type is called. This means it is an integer type.

### 1.10 Task 8

In this task, you'll determine the Boolean value that represents whether the current number of login attempts a user has made is less than or equal to the maximum number of login attempts allowed.

Be sure to replace each ### YOUR CODE HERE ### with your own code before you run the following cell.

#### True

#### Hint 1

In Python, you can use the <= comparison operator to determine whether one value is less than or equal to another value.

#### Hint 2

To determine whether the current number of login attempts a user has made is less than or equal to the maximum number of login attempts allowed, use the <= operator. Place login\_attempts to the left of the <= operator, and place max\_logins to the right of the <= operator.

To make sure the resulting Boolean value is displayed, write this code inside of the parantheses where print() is called.

### Question 6 What is the output? What does this mean?

The code print(login\_attempts  $\le$  max\_logins) asks the python machine is  $2 \le$  3 true? If so print true and if not print false. Since it prints true, this is a boolean type that outputs true for this statement  $2 \le$  3 or print(login\_attempts  $\le$  max\_logins)

#### 1.11 Task 9

This code continues to check for the Boolean value of whether max\_logins is less than or equal to login\_attempts. In this task, reassign other values to login\_attempts. For example, you might choose a value that is higher than the maximum number of attempts allowed. Observe how the output changes.

Be sure to replace each ### YOUR CODE HERE ### with your own code before you run the following cell.

#### False

Hint 1

To assign login\_attempts to a specific value, make sure to write the value to the right of the = operator.

# Question 7 Based on the different values you assigned to login\_attempts, what did you observe about the output?

The code print(login\_attempts  $\leq$  max\_logins) asks the python machine is  $7 \leq$  3 true? If so print true and if not print false. Since it prints false, this is a boolean type that outputs false for this statement  $7 \leq$  3 or print(login\_attempts  $\leq$  max\_logins)

#### 1.12 Task 10

Finally, you can also assign a Boolean value of True or False to a variable.

In this task, you'll create a variable called login\_status, which is a Boolean that represents whether a user is logged in. Assign False to this variable and store its data type in a variable called login\_status\_type and display it.

Be sure to replace each ### YOUR CODE HERE ### with your own code before you run the following cell.

```
[28]: # Assign `login_status` to the Boolean value False

login_status = False

# Assign `login_status_type` to the data type of `login_status`

login_status_type = type(login_status)

# Display `login_status_type`

print(login_status_type)
```

<class 'bool'>

Hint 1

To assign the Boolean value False to the login\_status variable, make sure to write False to the right of the = operator.

Hint 2

Note that Boolean values should not have quotation marks around them in code.

# Question 8 Based on the output above, what do you observe about the data type of login\_status?

After setting login\_status to False, and then find data type with login\_status\_type and then inserting the login\_status to it, it outputs <class 'bool'> when login\_status\_type is called. This means it is a bool type.

### 1.13 Conclusion

#### What are your key takeaways from this lab?

In this lesson, I learned about Python variables and data types. I practiced assigning values to variables like device\_id, username\_list, and max\_logins. I also explored different data types, including strings, lists, integers, and booleans, and used the type() function to check their types. I learned how to print and compare values using operators like <=, and how to manage Boolean values like True and False in conditions. The main takeaway is how important it is to understand data types and how to manipulate and check them in Python to perform various tasks like authentication or tracking login attempts.
